Executive Summary

This report presents an order-channel performance and market share analysis of 1,696 restaurant and bar branches operating under the SkyCity Auckland hospitality network. The analysis was produced as part of a Data Analyst internship project for Unified Mentor and is intended for two audiences: (1) restaurant operations and finance stakeholders, and (2) government and regulatory stakeholders with an interest in the health, resilience, and fairness of Auckland's food-delivery ecosystem.

The dataset spans four ordering channels — In-Store dining, Uber Eats, DoorDash, and Self-Delivery — across four Auckland subregions (CBD, North Shore, South Auckland, West Auckland), eight cuisine categories, and four restaurant business segments (Cafe, QSR, Full-service, Ghost Kitchen).

Headline Findings

- Delivery channels account for 82.5% of all orders network-wide, with Uber Eats alone responsible for 39.6% of total order volume — more than double any other single channel.
- Aggregator commissions materially compress margins: Uber Eats and DoorDash generate the highest revenue of any channel but return only a fraction of that as net profit, while In-Store and Self-Delivery orders are 25-30x more profitable per order.
- 603 restaurants (35.6% of the network) currently operate with combined Uber Eats + DoorDash dependence above 70%, a level at which a single aggregator policy or fee change could materially disrupt their revenue.
- No restaurant in the network breaches a 70% dependence on any single aggregator in isolation — the risk is concentrated, structurally, in combined reliance on the two largest platforms together.
- Network-wide 6-month order growth is projected at approximately +19%, with Uber Eats and DoorDash both growing faster than In-Store dining, reinforcing the shift toward delivery-first consumption.

Executive Summary Table

The table below reflects the live dashboard's Executive Overview at the time of writing, captured directly from the deployed application.

Metric	Value
Total Orders	2,019,134
Total Revenue	\$77,739,307
Total Net Profit	\$7,866,306
Overall Margin	10.12%
Avg Order Value	\$38.52
Restaurants in View	1,696
In-Store Share	17.5%
Delivery Share	82.5%

Figure 0.1 — Executive Summary Table, as rendered in the live SkyCity Auckland Channel Performance Analytics dashboard.

Why This Matters for Government and Regulatory Stakeholders

Auckland's hospitality sector is undergoing a structural shift from dine-in consumption toward third-party delivery platforms. This has three policy-relevant implications:

1. Market concentration risk: with two aggregators (Uber Eats and DoorDash) jointly responsible for the majority of delivery volume, and over a third of restaurants highly dependent on them, commission-rate policy at the platform level has an outsized effect on small-business viability.
2. Commission transparency: the data shows aggregator orders can generate 25-30x less profit per order than in-store or self-managed delivery, primarily due to commission rates of 28-33% charged by aggregators. This has direct relevance to ongoing public conversations around delivery-platform fee regulation.
3. Even distribution of digital economy benefits: the data shows meaningful geographic and cuisine-category variation in aggregator dependence, which may be useful in targeting small-business support programs toward the restaurants and subregions most exposed to platform-concentration risk.

Top Recommendations

1. Prioritize channel-diversification support (self-delivery enablement, in-store promotions) for the 603 restaurants flagged as high-risk (>70% combined aggregator dependence).
2. Use the dashboard's live forecast tooling to plan kitchen and delivery-fleet capacity ahead of the projected ~19% six-month growth in order volume, concentrated in aggregator channels.
3. Extend self-delivery capability in subregions and cuisine categories where it is currently under-represented, given it is the second most profitable channel per order after in-store dining.

1. Introduction and Background

The Auckland hospitality market has seen rapid growth in multi-channel ordering, driven by the expansion of food-delivery aggregators (Uber Eats, DoorDash), changing consumer preferences for convenience, and urban density differences across Auckland subregions. Restaurants operating under the SkyCity Auckland umbrella now operate across four parallel order channels — In-Store dining, Uber Eats, DoorDash, and Self-Delivery — each playing a different strategic role in customer reach, brand visibility, and volume generation.

Despite having detailed channel-level data, restaurant operators and analysts have historically lacked clear visibility into channel dependence, understanding of which channels dominate in which subregions, and insight into how cuisine type and restaurant segment influence channel mix. Without this knowledge, restaurants risk becoming over-dependent on aggregators, channel strategy decisions remain intuition-based rather than evidence-based, and market risks remain hidden until they materialize as margin pressure.

This project was undertaken as part of the Data Analyst internship program at Unified Mentor. It builds directly on feedback from a prior internship project (an APL Logistics profitability dashboard, evaluated 8/10), which recommended two specific improvements that this project explicitly addresses: (1) incorporating predictive analytics for demand and profit forecasting to enable proactive decision-making, and (2) adding drill-down functionality from summary KPIs down to individual-record level. Both recommendations are implemented in full — see Sections 7 and 8.

1.1 Problem Statement

Specifically, this project addresses three structural questions facing SkyCity Auckland restaurant operators:

- How is order volume, revenue, and profit distributed across the four ordering channels, and how does this vary by subregion, cuisine type, and business segment?
- Which restaurants are most exposed to aggregator-dependence risk, and what does a healthy versus high-risk channel mix look like?
- Given each restaurant's current growth trajectory, what does demand and profitability look like 3, 6, and 12 months forward, and which restaurants warrant proactive attention?

2. Project Objectives

2.1 Primary Objectives

- Quantify total order volume by channel across the network.
- Measure channel share distribution across restaurants, subregions, cuisines, and business segments.
- Identify dominant ordering channels by geography.

2.2 Secondary Objectives

- Compare channel mix across cuisine types.
- Assess channel diversification versus dependency risk at the individual-restaurant level.
- Support strategic channel planning with forecasting and drill-down tooling.

3. Dataset Description

The analysis is built on a single restaurant-level dataset of 1,696 restaurant branches, each described by 30 columns spanning identity, geography, cuisine, and full channel-level order, revenue, cost, and profit figures. There is no separate transaction-level or customer-level table — each row represents one restaurant's current monthly performance snapshot. This has a direct implication for two components of this analysis: forecasting (Section 7) uses compound growth projection rather than time-series decomposition, since no historical time series is provided; and drill-down (Section 8) operates at the restaurant level, since that is the finest granularity available.

Column	Description
RestaurantID	Unique identifier for each restaurant branch
RestaurantName	Name of the restaurant establishment
CuisineType	Category of food served (e.g., Burgers, Pizza)
Segment	Business model classification (e.g., Cafe, QSR)
Subregion	Geographical area within Auckland (CBD, North Shore, South Auckland, West Auckland)
GrowthFactor	Month-over-month growth multiplier (0.99 – 1.05)
AOV	Average order value per transaction (\$29.79 – \$47.23)
MonthlyOrders	Total transactions across all channels per month
InStoreOrders / UberEatsOrders / DoorDashOrders / SelfDeliveryOrders	Order counts by channel
InStoreRevenue / UberEatsRevenue / DoorDashRevenue / SelfDeliveryRevenue	Gross revenue generated by channel
COGSRate	Cost of Goods Sold as a percentage of revenue (20% – 40%)
OPEXRate	Operating expenses as a percentage of revenue (20% – 55%)
CommissionRate	Commission charged by third-party delivery platforms (28% – 33%)
DeliveryRadiusKM	Maximum delivery distance offered by the restaurant (3 – 18 km)
DeliveryCostOrder / SD_DeliveryTotalCost	Self-delivery cost per order / total monthly self-delivery cost
InStoreNetProfit / UberEatsNetProfit / DoorDashNetProfit / SelfDeliveryNetProfit	Net profit by channel (Revenue – COGS – OPEX [– Commission or Delivery Cost])
InStoreShare / UE_share / DD_share / SD_share	Provided channel-share fields (see Section 4.2 for a data-quality note on these)

4. Methodology

The analysis follows a seven-step forecasting and analytics methodology, implemented in a fully executed, reproducible Jupyter notebook (SkyCity_Channel_Analytics.ipynb, included in the project GitHub repository) and mirrored in the live Streamlit dashboard referenced in the Project Resources section.

4.1 Step-by-Step Methodology

1. Data Validation & Consistency Checks — verify channel order counts sum to MonthlyOrders; validate that channel share percentages reconcile to 100%; identify anomalies and outliers for transparency.
2. Channel Volume Aggregation — aggregate total orders by channel, subregion, cuisine, and restaurant segment.
3. Channel Market Share Analysis — compute overall channel market share; compare delivery versus in-store dominance; rank channels by order contribution.
4. Geographic Channel Preference Analysis — compare channel share across the four Auckland subregions; identify urban versus suburban ordering behaviour.
5. Cuisine & Segment Channel Patterns — analyze channel mix by cuisine and by business segment; identify aggregator-heavy cuisine categories.
6. Channel Dependency Risk Identification — flag restaurants with high reliance on a single or combined aggregator; define diversification benchmarks.
7. Growth & Demand Forecasting — project orders, revenue, and profit 3/6/12 months forward using each restaurant's own GrowthFactor, both network-wide and by channel.

4.2 Data Quality Finding

A material data-quality issue was identified and corrected during Step 1. The provided InStoreShare field is not on the same basis as the UE_share, DD_share, and SD_share fields: InStoreShare represents a restaurant's in-store orders as a percentage of total orders, while UE_share, DD_share, and SD_share each represent a channel's share of delivery orders only (i.e., they sum to 100% among themselves, excluding in-store). Summed naively, the four provided fields average roughly 142%, not 100%.

This analysis recomputes all channel shares directly from the underlying order-count columns (InStoreOrders, UberEatsOrders, DoorDashOrders, SelfDeliveryOrders, divided by MonthlyOrders) so that every share figure in this report and the accompanying dashboard is on a consistent, reconciled, total-order basis.

4.3 Analytical Tools

The underlying analysis was performed in Python (pandas, NumPy) with visualizations in Matplotlib and Seaborn for the notebook, and Plotly for the interactive dashboard. The dashboard itself is built in Streamlit and deployed publicly (see Project Resources).

5. Exploratory Data Analysis and Findings

This section presents the core exploratory findings, organized to mirror the structure of the live dashboard. Every figure below is a real screenshot captured from the deployed application (see Project Resources), reflecting live, filterable data rather than static charts.

5.1 Executive Overview

The Executive Overview module gives a single-page financial snapshot of the network: revenue and profit by channel, restaurant segment composition, the distribution of profit margins across the network, and the highest-performing restaurants by net profit.

Figure 5.1 — Revenue vs. Net Profit by channel (left) and restaurant segment mix (right).

Uber Eats generates the highest gross revenue of any channel by a wide margin, but its net-profit bar is barely visible on the same axis — a direct visual illustration of commission-driven margin compression. QSR (32.0%) and Cafe (29.7%) are the two largest business segments by restaurant count, followed by Full-service (26.7%) and Ghost Kitchen (11.6%).

Figure 5.2 — Distribution of net profit margin across all 1,696 restaurants (left) and the top 10 restaurants by net profit (right).

The profit-margin distribution is notably bimodal, with a smaller cluster of restaurants operating at negative-to-low margins (roughly -15% to 0%) and a larger, dominant cluster centered around 10-20%. This bimodality is explored further in Section 6, where it is shown to correlate strongly with restaurant business segment — Full-service restaurants disproportionately populate the lower, loss-making cluster.

5.2 Channel Mix Overview

Figure 5.3 — Total order volume by channel (left) and overall channel market share (right).

Uber Eats is the single largest channel by order volume (800,353 orders, 39.6% market share), more than double DoorDash (436,135 orders, 21.6%) and comfortably ahead of Self-Delivery (411,255 orders, 20.4%) and In-Store (371,391 orders, 18.4%). Combined, the three delivery channels account for 82.5% of order volume network-wide.

Figure 5.4 — In-store vs. combined delivery order volume (left) and net profit per order by channel (right).

Delivery channels collectively outpace in-store dining by 4.4x in order volume. Critically, the profit-per-order chart reveals the inverse relationship in unit economics: In-Store orders return \$10.31 in profit per order and Self-Delivery returns \$8.82, while Uber Eats returns just \$0.32 and DoorDash \$0.35 per order — roughly 25-30x less profitable per unit than the two non-aggregator channels, driven by commission rates of 28-33%.

Figure 5.5 — Order volume by channel, broken down by restaurant business segment.

Ghost Kitchen restaurants show the most extreme channel concentration, with in-store representing a negligible share of their order volume (as expected, since ghost kitchens have no dine-in service) and Uber Eats dominating. Cafe, Full-service, and QSR segments show more balanced four-channel mixes, though all three still lean toward delivery over in-store.

5.3 Geographic Channel Preference Analysis

Channel preference varies only modestly across Auckland's four subregions (CBD, North Shore, South Auckland, West Auckland) — a somewhat unexpected finding, given the guideline's hypothesis of pronounced urban-versus-suburban variation.

Figure 5.6 — Channel share (%) by subregion, heatmap view.

Uber Eats commands 39.6-39.7% share consistently across all four subregions, with only fractional variation. This suggests Uber Eats' market position in Auckland is not geographically driven but reflects network-wide brand and platform dominance.

Figure 5.7 — Total orders by subregion (left) and revenue & profit by subregion (right).

West Auckland leads in order volume (552,503 orders) followed closely by South Auckland (529,249), with CBD (473,976) and North Shore (463,406) somewhat lower. Notably, West Auckland and South Auckland also lead in revenue and profit, indicating that order-volume leadership is translating into proportional financial performance in these subregions.

Figure 5.8 — Combined aggregator-delivered order share by subregion.

Aggregator-delivered share (Uber Eats + DoorDash combined) ranges narrowly from 61.1% (North Shore) to 61.4% (CBD) across all four subregions — a difference of just 0.3 percentage points. This near-uniformity across a dense urban core (CBD) and outer suburban subregions (West/South Auckland, North Shore) indicates that aggregator dependence in this network is a structural, network-wide characteristic rather than a localized geographic pattern.

5.4 Cuisine & Segment Channel Patterns

Figure 5.9 — Channel mix by cuisine type, ranked by in-store share.

Burgers and Chicken Dishes show the strongest in-store presence among all cuisine categories, while Pizza stands out for its unusually high self-delivery share — consistent with pizza chains' long history of operating their own delivery fleets independent of aggregators.

Figure 5.10 — Most aggregator-dependent cuisine categories (left) and channel mix by restaurant segment (right).

Kebabs/Mediterranean and Japanese cuisine are the most aggregator-dependent categories, both at 74.2% combined Uber Eats + DoorDash share, followed by Thai (70.1%) and Indian (70.0%). Pizza is the clear outlier at the opposite end, at just 41.9% aggregator share — again reflecting its distinct self-delivery model. By segment, Ghost Kitchen shows the leanest in-store presence and the heaviest reliance on Uber Eats specifically, consistent with its delivery-only business model.

Figure 5.11 — Average order value (AOV) by cuisine type.

AOV is remarkably consistent across cuisine categories, ranging narrowly from \$38.07 (Kebabs/Mediterranean) to \$38.79 (Chicken Dishes) — a spread of less than \$1. This suggests menu pricing and typical basket size are standardized network-wide rather than varying meaningfully by cuisine.

6. Channel Dependency Risk Analysis

A restaurant that relies too heavily on a small number of delivery aggregators is structurally exposed to that platform's commission-rate policy, algorithm changes, or service disruptions. This section quantifies that exposure across the network using two complementary metrics: a literal single-aggregator threshold (as specified in the original project guideline) and a more informative combined-aggregator dependence index.

Figure 6.1 — Channel-risk profile across the network (left) and distribution of the Channel Diversification Score (right).

Figure 6.2 — Restaurants exceeding the 70% dependence threshold, by definition.

Two important findings emerge from this analysis. First, not a single restaurant in the network exceeds 70% reliance on any one aggregator in isolation — the maximum single-channel (Uber Eats) share observed is well below that threshold. Second, and more materially, 603 restaurants (35.6% of the network) exceed 70% combined Uber Eats + DoorDash dependence. This confirms that the literal single-aggregator risk definition in the original guideline understates real-world exposure for this dataset — combined aggregator dependence is the metric that should drive risk-management decisions.

The network splits into three risk bands: 286 restaurants (16.9%) are Balanced, with under 50% combined aggregator dependence; 807 restaurants (47.6%) fall into a Moderate band (50-70%); and the remaining 603 (35.6%) are High Risk. The Channel Diversification Score — a normalized Herfindahl-Hirschman Index where 1.0 represents a perfectly even four-channel split — shows most of the network clustered between 0.85 and 0.95, indicating that even 'balanced' restaurants in this dataset still lean toward delivery channels rather than achieving a truly even four-way split.

Figure 6.3 — Risk scatter of aggregator dependence versus profit margin, colored by restaurant segment, sized by monthly order volume.

This scatter view is one of the dashboard's most actionable diagnostics. Full-service restaurants (orange) cluster distinctly in the negative-to-low margin band regardless of their aggregator dependence, indicating that Full-service as a segment faces structural margin pressure independent of channel mix — likely reflecting a higher cost base (dine-in staffing, real estate) that isn't offset by delivery revenue. QSR, Cafe, and Ghost Kitchen segments, by contrast, maintain positive margins across the full range of aggregator dependence, though even within these segments, margin trends gently downward as dependence crosses the 70% threshold.

7. Growth and Demand Forecasting

As recommended in the prior project evaluation, this analysis extends beyond descriptive reporting into predictive analytics. Because the dataset provides a per-restaurant GrowthFactor (a month-over-month multiplier between 0.99 and 1.05) rather than a historical time series, compound growth projection — rather than time-series decomposition — is the statistically appropriate forecasting method for this data shape.

7.1 Network-Wide Forecast

Figure 7.1 — Compound growth forecast for orders, revenue, and net profit, with an adjustable 1-24 month horizon (shown here at 6 months).

At a 6-month horizon, the network is projected to grow from 2,019,134 to 2,407,907 monthly orders (+19.3%), from \$77.7M to \$93.0M in monthly revenue (+19.6%), and from \$7.9M to \$9.4M in monthly net profit (+20.1%). The dashboard's forecast horizon is user-adjustable from 1 to 24 months, allowing operations and finance stakeholders to plan capacity against different time horizons interactively.

7.2 Channel-Level Forecast

Figure 7.2 — Channel-level 6-month growth outlook, with a data table of current versus projected orders per channel.

Growth is broadly uniform across channels at a 6-month horizon (approximately +19.2% to +19.4% for every channel), meaning the current channel mix — and by extension, the current aggregator-dependence risk profile documented in Section 6 — is expected to persist rather than self-correct. Of the 1,696 restaurants in the network, 410 (24.2%) show a declining GrowthFactor below 1.0, while 1,286 (75.8%) are trending upward, providing a clear, prioritized list for retention-focused intervention.

8. Restaurant-Level Drill-Down and Lifetime Value

The second improvement recommended in the prior project evaluation was drill-down functionality from summary KPIs down to individual-record level. Because this dataset's finest available granularity is the individual restaurant branch (no transaction-level feed is provided), the dashboard's Restaurant Explorer module implements this drill-down at the restaurant level — the closest achievable analogue for this data shape.

Figure 8.1 — Restaurant Explorer: a searchable, sortable table of all 1,696 restaurants with revenue, profit, margin, aggregator dependence, and a projected 12-month value column.

Every restaurant in the network can be searched by name and sorted by any metric. A Projected 12-Month Value column is included as a restaurant-level analogue to customer lifetime value (another improvement area flagged in the prior evaluation, adapted here to a dataset with no individual-customer records): it compounds each restaurant's own net profit forward using its GrowthFactor across a 12-month horizon, giving stakeholders a forward-looking view of each restaurant's cumulative financial contribution, not just its current-month snapshot.

8.1 Single-Restaurant Example

Figure 8.2 — Single-restaurant drill-down example: Bombay Bistro, showing per-channel order, revenue, and profit breakdown.

Selecting any restaurant surfaces its individual channel breakdown. In the example above (Bombay Bistro, Indian cuisine, Full-service, North Shore), the restaurant carries a monthly net loss of $-\$1,395$ despite $\$36,346$ in monthly revenue, driven primarily by unprofitable Uber Eats and DoorDash orders that outweigh a modest In-Store profit. Its projected 12-month value is correspondingly negative ($-\$19,796$), flagging it as a clear candidate for margin-improvement intervention — precisely the kind of individual-record insight that network-level KPIs alone would not surface.

9. Key Insights

1. Delivery dominates volume, but not profit. Aggregator and self-delivery channels together account for 82.5% of monthly orders, yet Uber Eats and DoorDash return only \$0.32–\$0.35 in profit per order versus \$8.82–\$10.31 for Self-Delivery and In-Store — a 25-30x profitability gap driven by 28-33% commission rates.
2. Combined aggregator dependence, not single-platform dependence, is the real risk signal. No restaurant exceeds 70% reliance on any one aggregator alone, but 603 restaurants (35.6%) exceed that threshold when Uber Eats and DoorDash are considered together.
3. Full-service restaurants face structural margin pressure independent of channel strategy. This segment clusters in negative-to-low profit margins across the entire aggregator-dependence spectrum, pointing to cost-base issues (likely staffing and real estate) rather than channel mix as the primary margin driver.
4. Geographic variation in channel preference is minimal. Aggregator-delivered share varies by only 0.3 percentage points across Auckland's four subregions, indicating that channel behaviour in this network is driven by network-wide platform dynamics rather than local urban/suburban differences.
5. Cuisine category is a stronger predictor of aggregator dependence than geography. Aggregator share ranges from 41.9% (Pizza) to 74.2% (Kebabs/Mediterranean and Japanese) — a 32-point spread, versus a 0.3-point spread across subregions.
6. Growth is broadly uniform across channels, meaning today's risk profile is likely to persist. All four channels are projected to grow ~19% over 6 months, so the current 35.6% high-risk restaurant share will not self-correct without intervention.
7. A data-quality issue in the source InStoreShare field was identified and corrected (see Section 4.2), and all reported shares in this document use the reconciled, total-order-basis calculation.

10. Recommendations

10.1 For Restaurant Operators

1. Prioritize the 603 high-risk restaurants (>70% combined aggregator dependence) for targeted diversification support — in-store promotions, loyalty programs, or self-delivery fleet investment — using the dashboard's Restaurant Explorer to identify and rank candidates.
2. Investigate the Full-service segment's structural margin issue independent of channel strategy; the data suggests cost-base review (staffing, occupancy) will yield more improvement than channel-mix changes alone for this segment.
3. Extend self-delivery capability to cuisine categories currently underweight in that channel (particularly Japanese, Thai, Indian, and Kebabs/Mediterranean, which show the highest aggregator dependence), following the Pizza category's playbook.

10.2 For Finance and Operations Planning

1. Use the dashboard's adjustable forecast horizon to align kitchen capacity, staffing, and delivery-fleet planning with the projected ~19% six-month growth in order volume.

2. Track the Projected 12-Month Value metric for individual restaurants (Section 8) to prioritize margin-improvement interventions proactively, rather than reactively after a restaurant turns unprofitable.

10.3 For Policy and Regulatory Stakeholders

1. Given that over a third of restaurants in this sample are highly dependent on two aggregator platforms, commission-rate policy at the platform level should be recognized as having a materially disproportionate effect on small-hospitality-business viability in Auckland.
2. Consider commission-rate transparency requirements or caps as a policy lever, given the demonstrated 25-30x profitability gap between aggregator and non-aggregator order channels documented in this analysis.
3. Small-business support programs (grants, low-interest financing for self-delivery infrastructure) could be targeted using aggregator-dependence data of the kind demonstrated in this dashboard, prioritizing the cuisine categories and restaurants shown to be most exposed.

11. Conclusion

This analysis delivers a clear, structured understanding of channel performance and market share across the SkyCity Auckland restaurant and bar network. By revealing how ordering behaviour varies — and, just as importantly, where it does not vary — across channels, cuisines, and regions, it equips restaurant operators, finance teams, and policymakers to design more balanced, resilient, and informed channel strategies in an increasingly delivery-driven market.

The project directly addresses both improvement areas flagged in the prior internship evaluation: predictive analytics (Section 7, compound growth forecasting for demand and profit) and drill-down functionality (Section 8, restaurant-level Explorer with a lifetime-value analogue). Combined with the data-quality correction documented in Section 4.2 and the risk-quantification framework in Section 6, this analysis aims to move channel-strategy decisions at SkyCity Auckland from an intuition-based to an evidence-based process.

Appendix A: Full KPI Summary Table

KPI	Value
Total Monthly Orders (network)	2,019,134
Total Revenue	\$77,739,307
Total Net Profit	\$7,866,306
Overall Profit Margin	10.12%
Average Order Value	\$38.52
In-Store Share	17.5%
Delivery Share (Uber Eats + DoorDash + Self-Delivery)	82.5%
Uber Eats Market Share	39.6%
DoorDash Market Share	21.6%
Self-Delivery Market Share	20.4%
Restaurants with >70% single-aggregator dependence	0
Restaurants with >70% combined aggregator dependence	603 (35.6%)
6-Month Network Order Growth (projected)	+19.3%
6-Month Network Revenue Growth (projected)	+19.6%
6-Month Network Net Profit Growth (projected)	+20.1%
Restaurants trending upward (GrowthFactor > 1.0)	1,286 (75.8%)
Restaurants trending downward (GrowthFactor < 1.0)	410 (24.2%)

Appendix B: Data Dictionary Reference

A complete column-by-column data dictionary is provided in Section 3 (Dataset Description) and is reproduced in full in the project's Jupyter notebook (SkyCity_Channel_Analytics.ipynb) and GitHub repository README.
